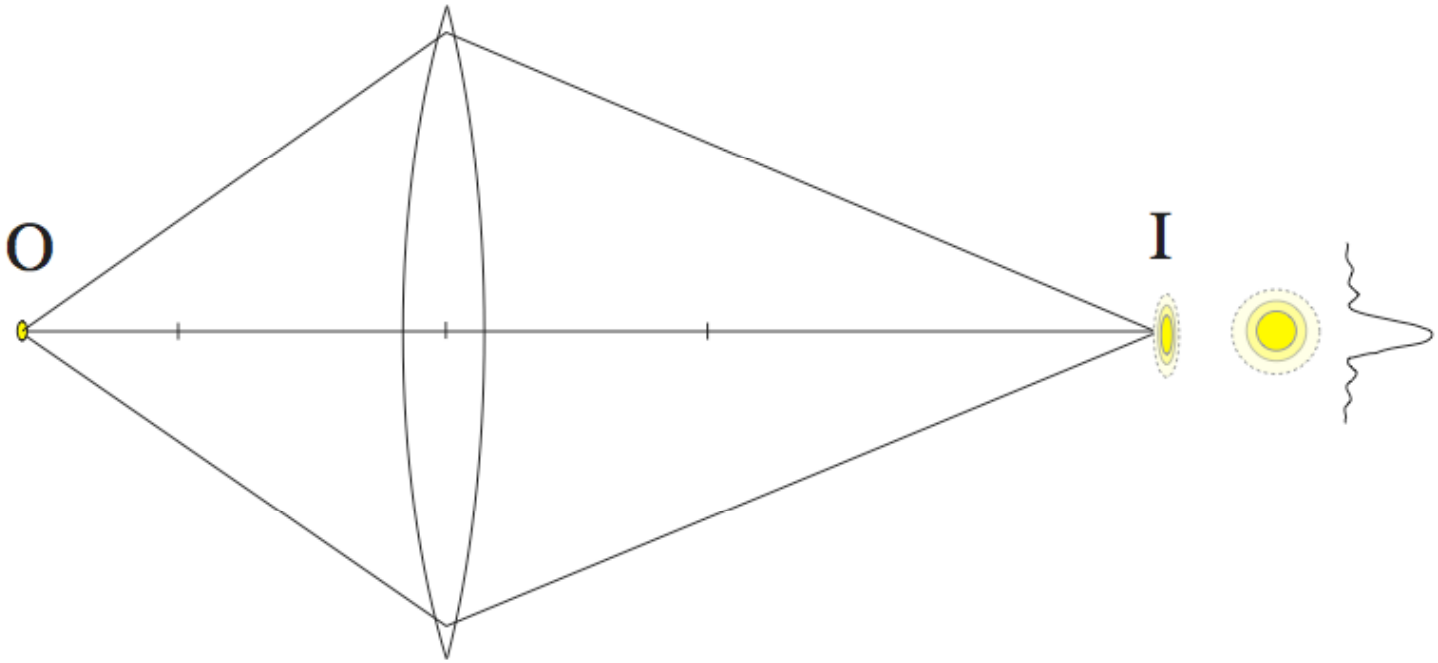
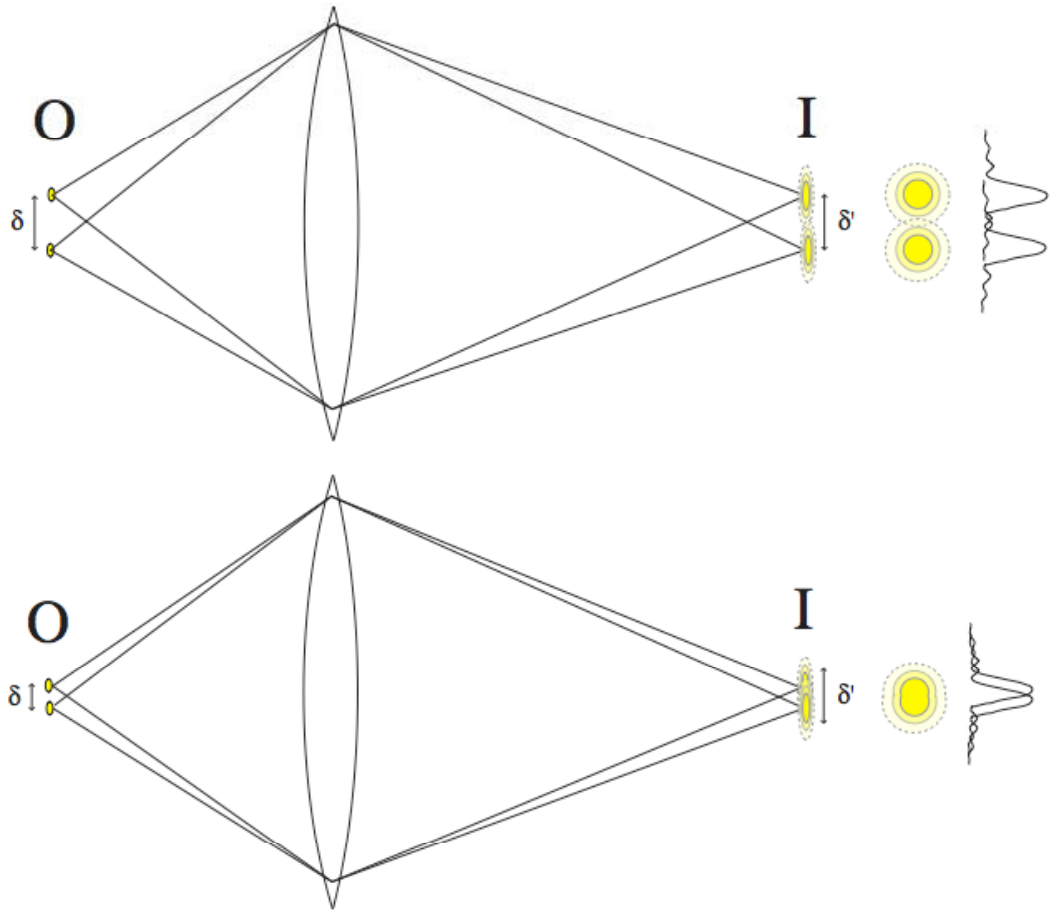
In ⊿ABC、AB Sin∖ = BC ∴ δ Sin∖ = λ. Then δ =λ / Sin∖ (0<θ<□/2) When refractive index of substance between lens and lattice is n, wave length is λ /n. Therefore δ = λ / n Sin∖

In previous slide, relation between lattice constant and wavelength in diffraction was shown. This equation is the same to resolution limit by Ernst Abbe, 1840-1905. That is, it appears that lattice is specimen, and also diffraction angle θ is incident light angle against the lens.

If the largest angle of incident light to the lens is θ_0, $n\mathrm{Sin}\theta_0$ is the numerical aperture of this lens. Then, lattice constant (δ_0) equal to the resolution of the lens. $\delta_0 = \lambda / n\ \mathrm{Sin}\theta_0$ This is a primitive equation on resolution of optical lens by Abbe. He think that resolution is determined by wave length used and numerical aperture of lens.



Imaging of very small bright spot through the lens. Right inset shows focused image (airy disk)



This cartoon shows resolution of two airy disks. In order to discriminate two airy disks distinctly, center of each airy disk must be separated more than half diameter (Lord Rayleight, 1842-1919).

Condenser lens is partially involved in resolution of microscope in a strict sense as well. Limited coherence κ (ratio of numerical aperture of objective and condenser lenses) affects the resolution of microscope as a whole. Therefore, Hopkins defines a following equation in general.

$$\delta_o = \kappa \lambda / n \sin\theta_0$$

κ changes by optical condition.

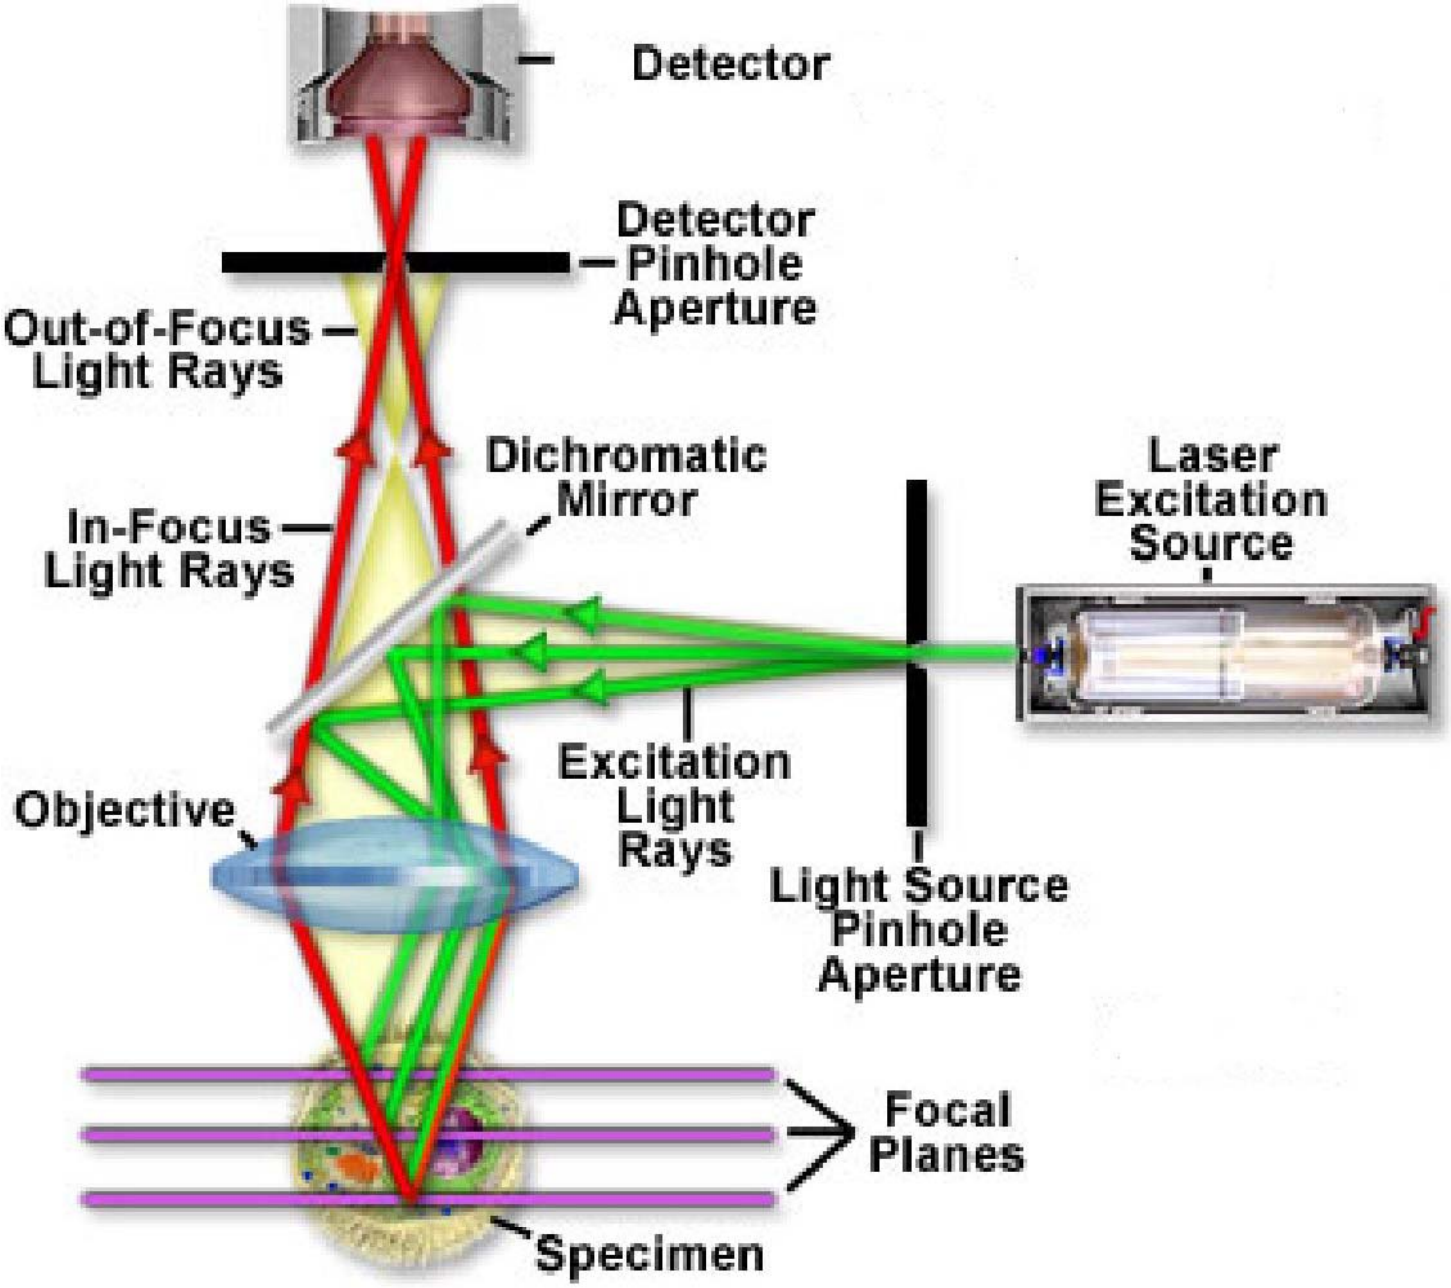
Confocal microscope

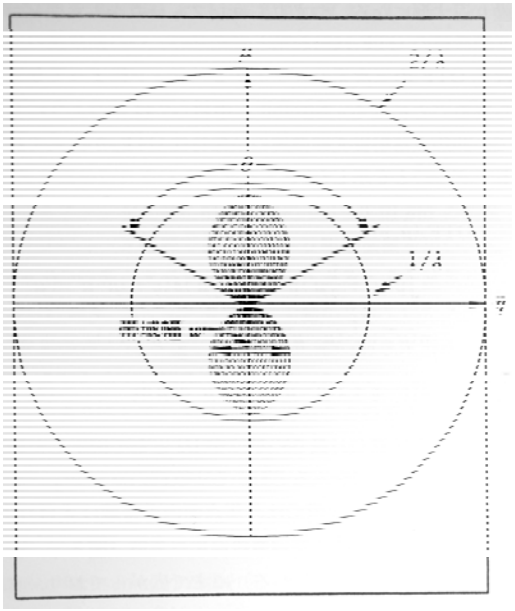


Advantage of confocal optics

1. 3D imaging
2. Tomography
3. Contrast enhancement by reduction of noise

OTF in conventional microscope

$$\mathrm{OTF}\ n\ (\mu,\eta) = \int p(\mu'+1/2\mu)p^*(\mu'-1/2\mu)\delta(\eta+\lambda\mu \cdot \mu')d^2\mu'$$



Confocal Optics (OTF)

$$\mathrm{OTF}\ c\ (\mu,\eta) = \int p(\mu''+1/2\mu')p^*(\mu''-1/2\mu')\delta(\eta'+\lambda\mu' \cdot \mu'')d^2\mu \cdot p(\mu'''+1/2(\mu-\mu'))\ p^*(\mu'''-1/2(\mu-\mu')) \cdot \delta(\eta-\eta'+\lambda(\mu-\mu')\ \mu''')\ d^2\ \mu'''d^2\eta'$$

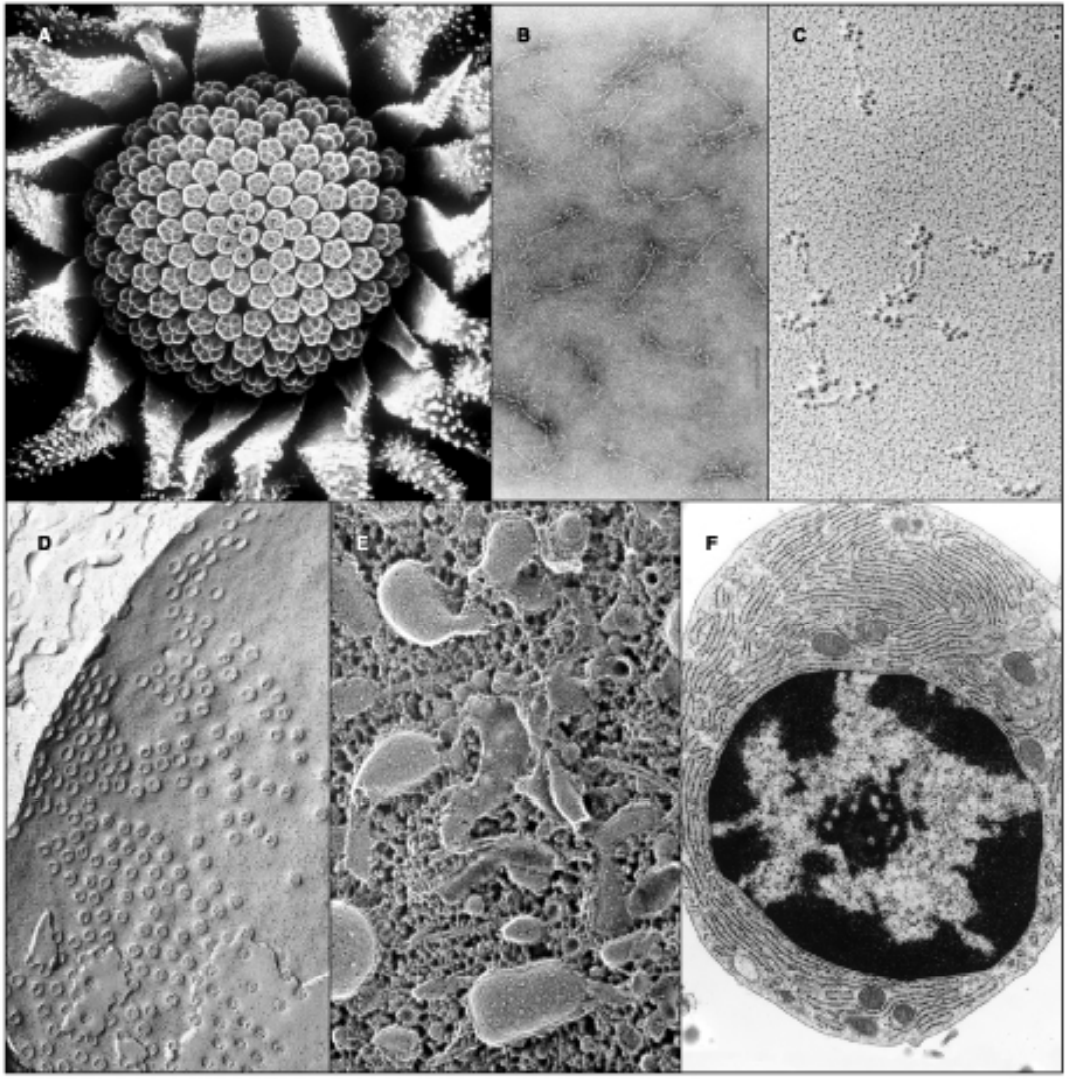
Structural information is different by methods in electron microscopy



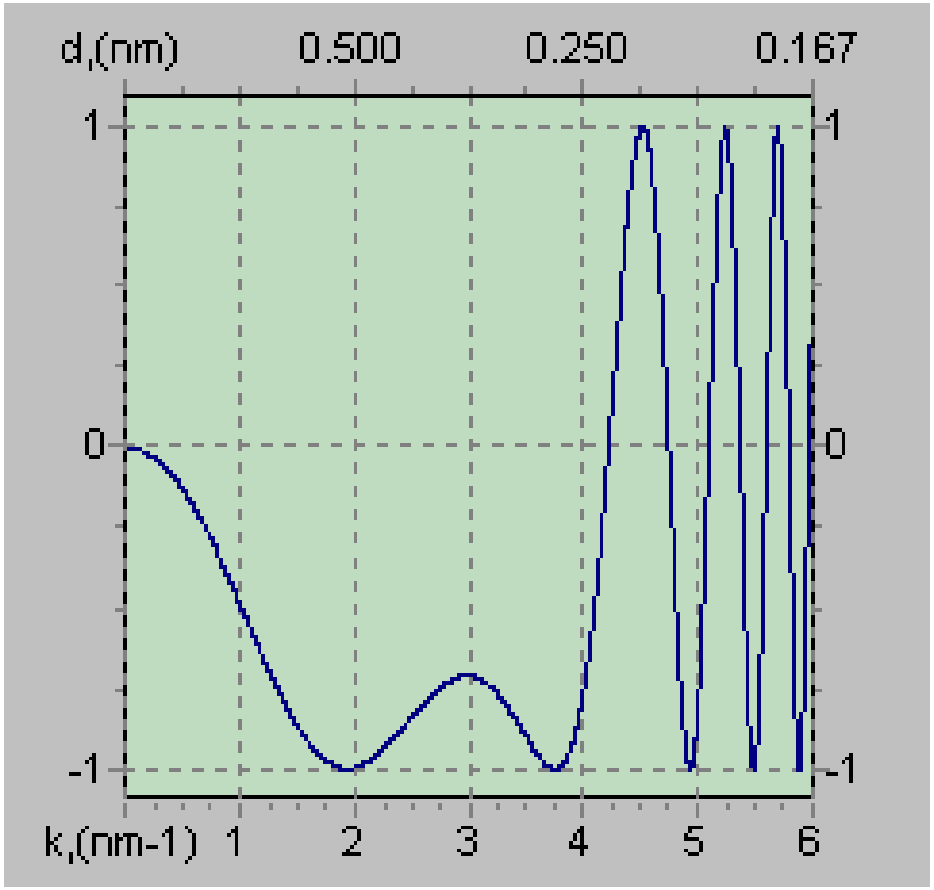
$$T(k) = -\sin\left[\frac{\pi}{2} C_s \lambda^3 k^4 + \pi \Delta f \lambda k^2\right]$$

Minus is positive contrast
Plus is negative contrast

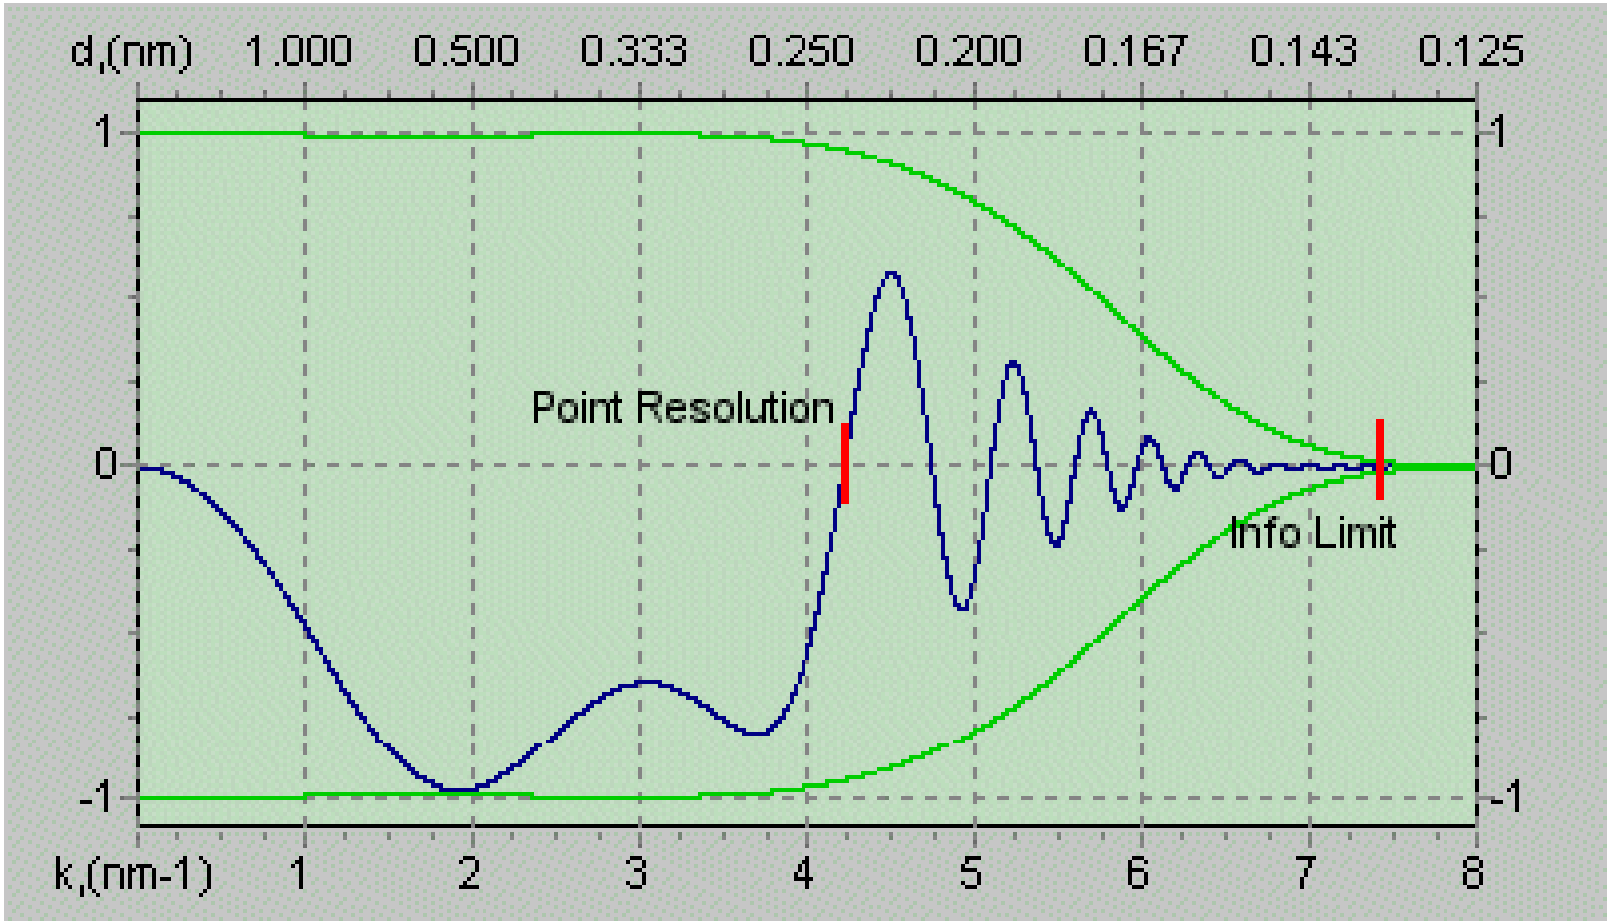
Oscillation is not maintained, and terminate to zero by Envelope Function as follows.

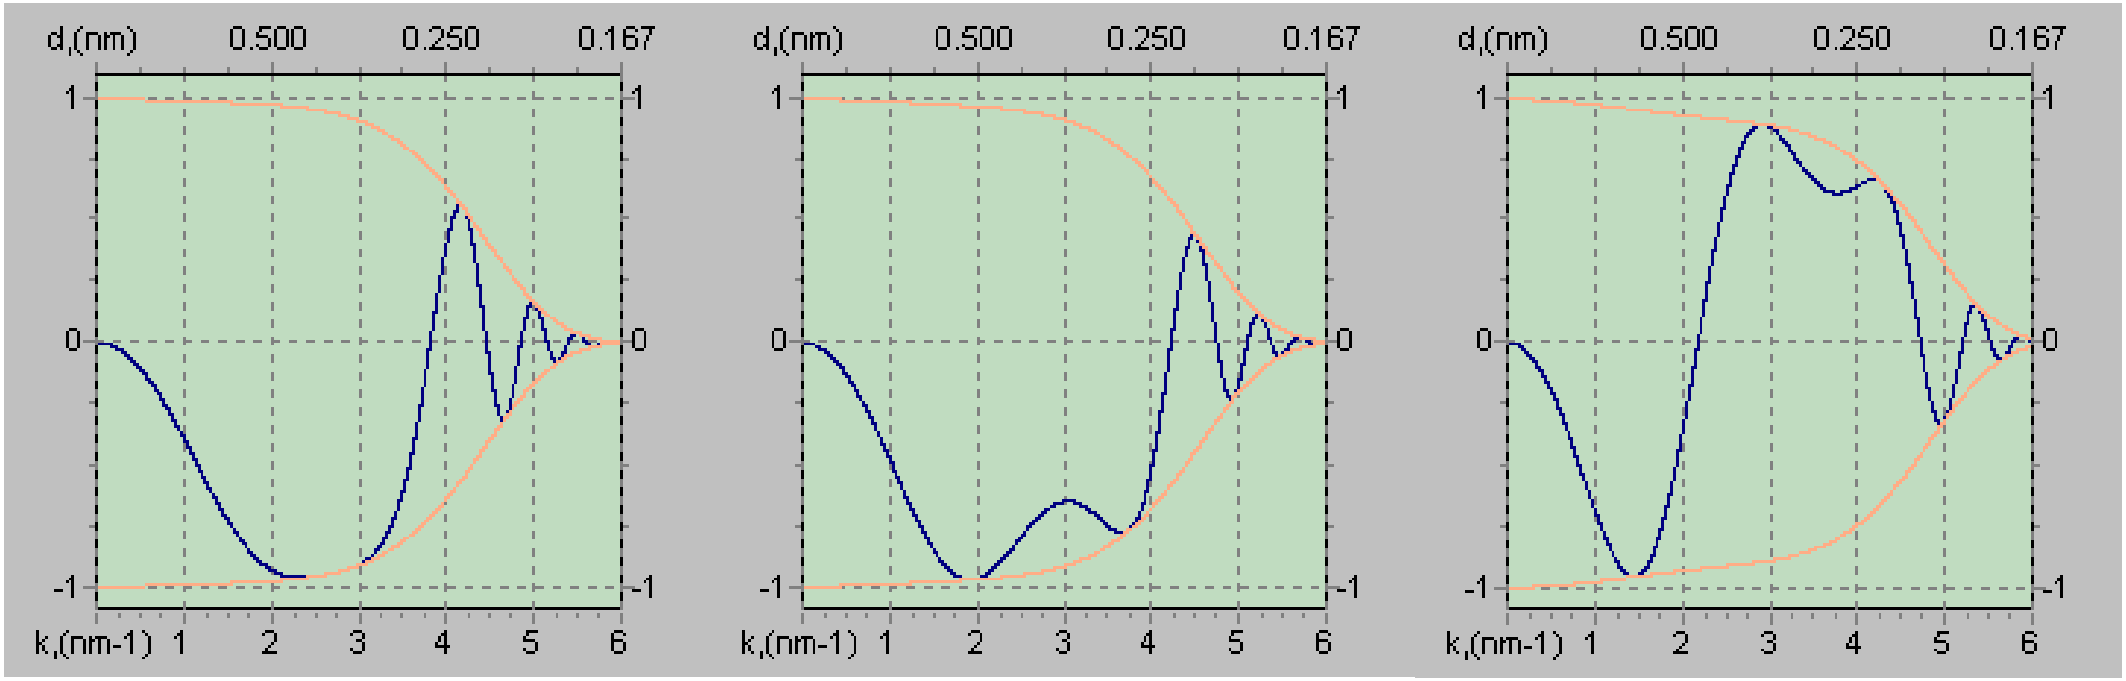
$$T(k)_{eff} = T(k) E_c E_a$$

Temporal coherency envelope
Spatial coherency envelope



$$r_{sch} = 0.66 C_s^{1/4} \lambda^{3/4}$$





Defocus: 1 scherzer ("True" Scherzer defocus)

1.2 scherzer ("Extended" Scherzer defocus). In general, this is the best defocus to take HR-TEM images.

Defocus: 1.9 scherzer
CTF is positive so that it produces a negative phase contrast ("white atoms")

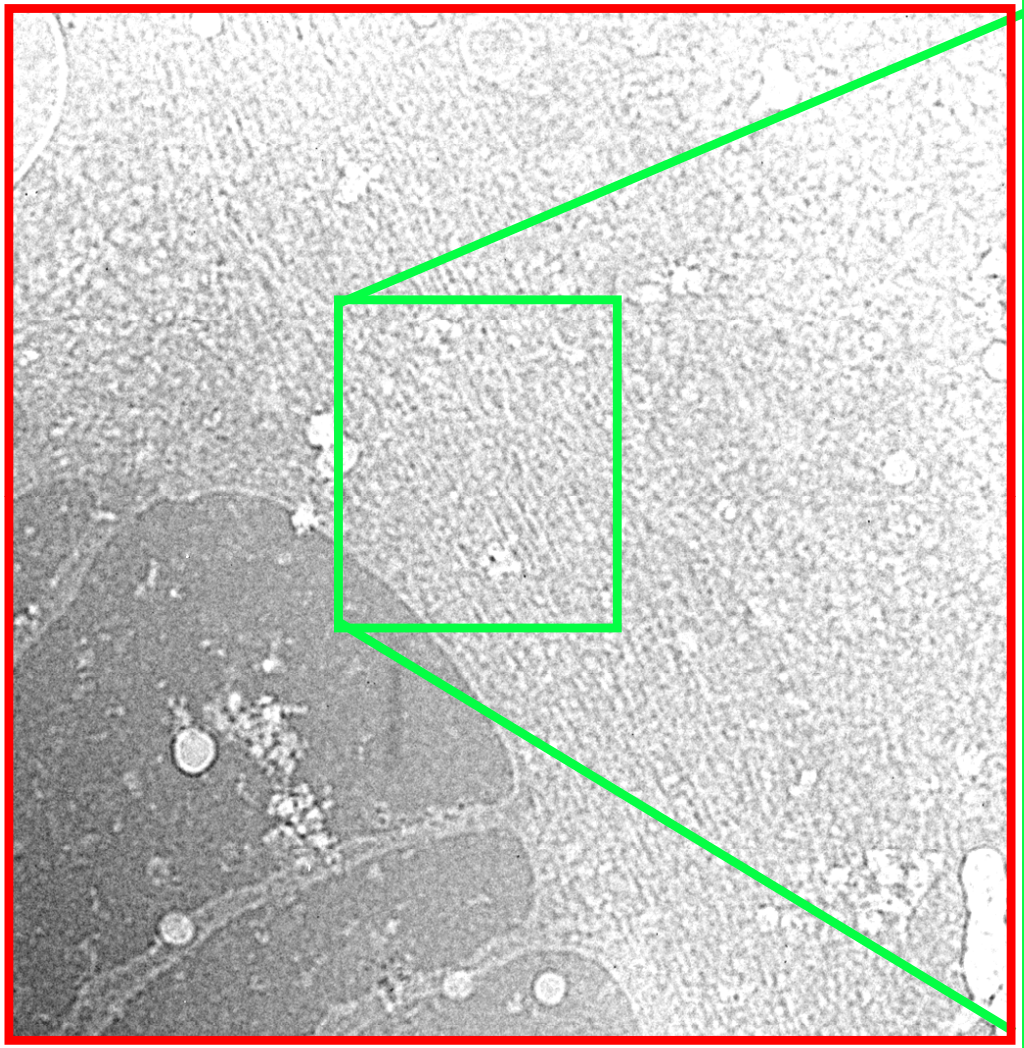
Observation condition

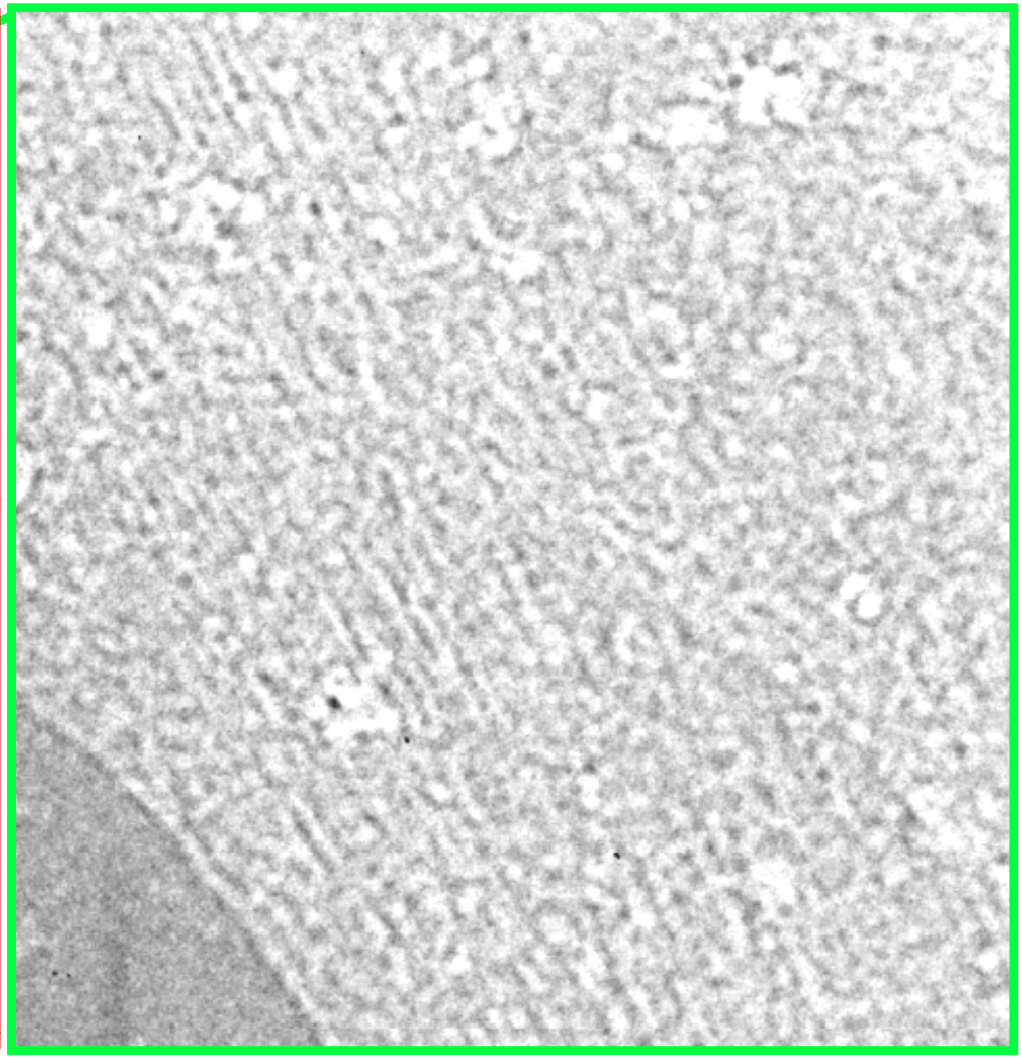
Acceleration voltage: 300 kV

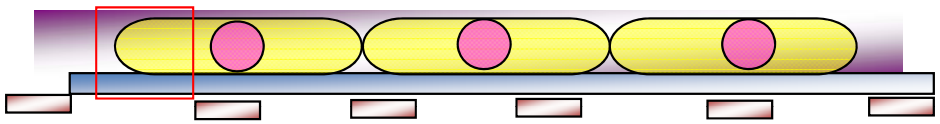
Temperature: 10 K (-263 ºC)

Image recording: CCD(2K×2K)

Whole cell observation

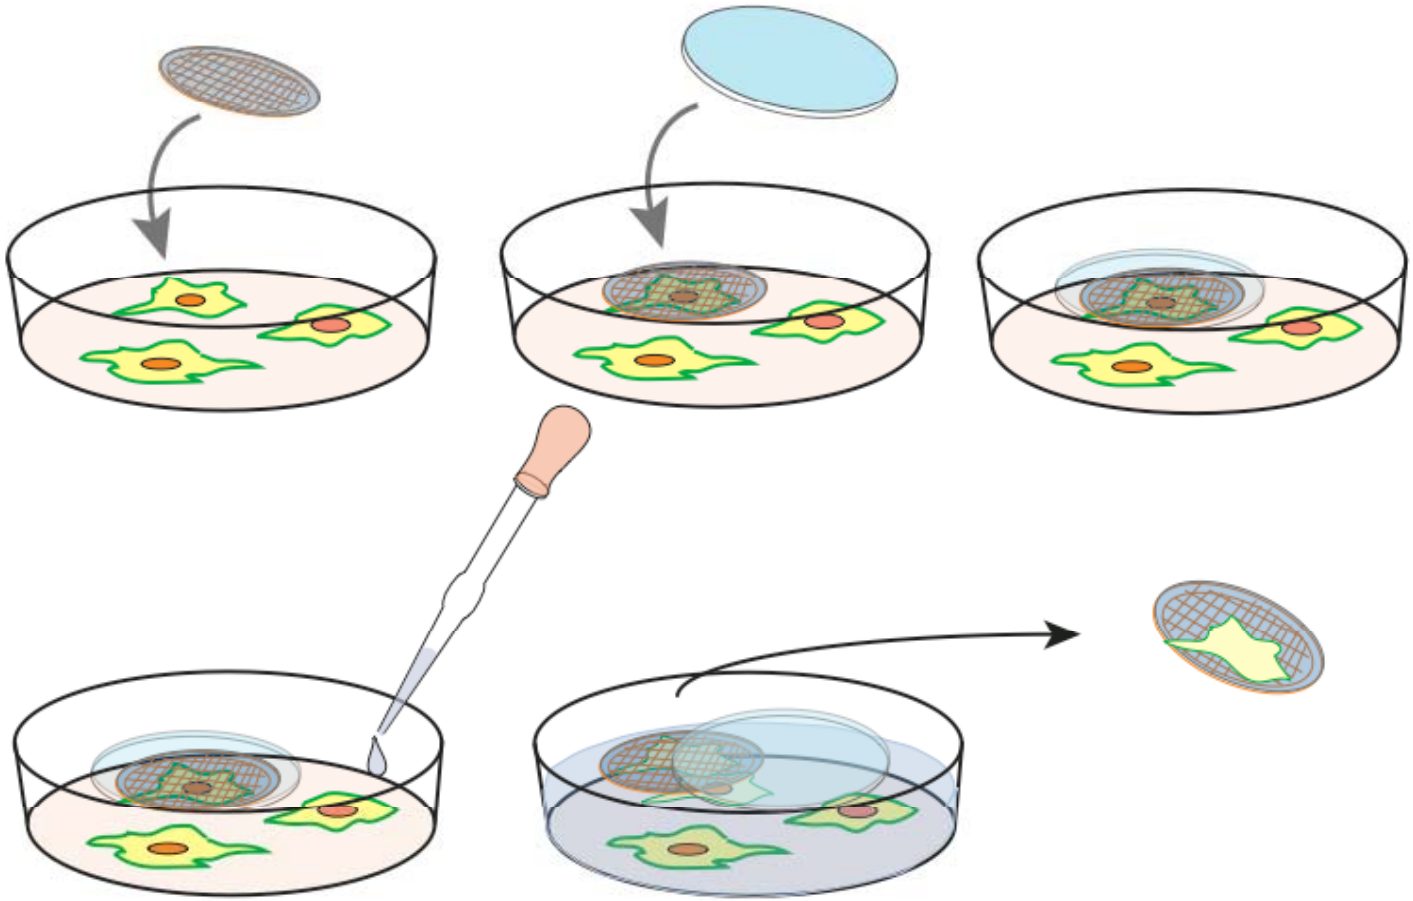






It is impossible to observe fine structure because of much amount of residual cytoplasm.

Our innovation is how apical membrane cytoskeletons of cells are isolated onto a mesh.



1. Culture medium is removed and washed once with Ringer's solution.
2. A sticky mesh is placed on the cells and covered with a small glass cover slip.
3. The mesh is slowly lifted by pouring Ringer's solution.
4. The apical membrane cytoskeleton is adherent to the mesh.

Cryoelectron micrograph of hydrated native membrane cytoskeleton
